## Introduction

## Changelog

### v0.26.0

- Completely redesigned and much improved support for Django models and QuerySets.
- Fix the `startunicorn` command and add some ascii art.

*All changes since 0.24.0.*

### v0.25.0

- Support calling functions in JavaScript modules.
- Fix: use `unicorn:db` without a `unicorn:model` in the same element.

*All changes since 0.24.0.*

### v0.24.0

- Support custom CSRF headers set with `CSRF_HEADER_NAME` setting.

*All changes since 0.23.0.*

### v0.23.0

- Performance enhancement that returns a 304 HTTP status code when an action happens, but the content doesn't change.
- Add `unicorn:ignore` attribute to prevent an element from being morphed (useful when using Unicorn with libraries like Select2 that change the DOM).
- Add support for passing arguments to `Unicorn.call`.
- Bug fix when attempting to cache component views that utilize the `db_model` decorator.

*All changes since 0.22.0.*

### v0.22.0

- Use Django cache for storing component state when available
- Add support for Django 2.2.x

*All changes since 0.21.2.*

### v0.21.2

- Add backported `dataclasses` for Python 3.6. (@frbor)

*All changes since 0.21.0.*

### v0.21.0

- Bug fix: Prevent disabled polls from firing at all.
- Support `Decimal` field type.
Introduction

- Support dataclass field type.
- Use type hints to cast fields to primitive Python types if possible.

All changes since 0.20.0.

**v0.20.0**

- Add ability to exclude component view properties from JavaScript to reduce the amount of data initially rendered to the page with `javascript_exclude`.
- Add `complete`, `rendered`, `parent_rendered` component hooks.
- Call JavaScript functions from a component view’s method.

All changes since 0.19.0.

**v0.19.0**

- Re-implemented how action method parsing is done to remove all edge cases when passing arguments to component view methods. (@frbor).
- Add support for passing kwargs to component view methods.

All changes since 0.18.1.

**v0.18.1**

- Fix regression where component kwargs were getting lost (<a href=https://github.com/adamghill/django-unicorn/issues/140>#140</a>, <a href=https://github.com/adamghill/django-unicorn/issues/141>#141</a>)
- Fix <code>startunicorn</code> management command (<a href=https://github.com/adamghill/django-unicorn/issues/142>#142</a>)

All changes since 0.18.0.

**v0.18.0**

- Only send updated data back in the response to reduce network latency.
- Experimental support for queuing up requests to alleviate race conditions when functions take a long time to process.
- Use type hints on component view attributes if needed.
- Bug fix: prevent race condition where an instantiated component class would be inadvertently re-used for component views that are slow to render
- Bug fix: use the correct component name to call a component method from “outside” the component.
- Deprecated: DJANGO_UNICORN setting has been renamed to UNICORN.

All changes since 0.17.2.

**v0.17.2**

- Don’t send the parent context in the response for child components that specify a partial update.
- Add support for element models to specify a partial update.
- Add support for polls to specify a partial update.
- Handle `date`, `time`, `timespan` when passed as arguments from JavaScript.
Introduction

- Render child component template’s JavaScript initialization with the parent’s as opposed to inserting a new script tag after the child component is rendered.
- Bug fix: prevent an error when rendering a Django model with a date-related field, but a string value.

All changes since 0.17.1.

**v0.17.1**

- Remove stray print statement.
- Fix bug where child components would sometimes lose their action events.

All changes since 0.17.0.

**v0.17.0**

- Target DOM changes from an action to only a portion of the DOM with partial updates.

All changes since 0.16.1.

**v0.16.1**

- Remove debounce from action methods to reduce any perceived lag.

All changes since 0.16.0.

**v0.16.0**

- Dirty states for when there is a change that hasn’t been synced yet.
- Add support for setting multiple classes for loading states.
- Attempt to handle when the component gets out of sync with an invalid checksum error.
- Performance tweaks when there isn’t a change to a model or dbModel with lazy or defer modifiers.

All changes since 0.15.1.

**v0.15.1**

- Fix bug where a component name has a dash in its name

All changes since 0.15.1.

**v0.15.0**

- Add support for child components
- Add discard action modifier
- Add support for referring to components in a folder structure
- Remove restriction that component templates must start with a div
- Remove restriction that component root can’t also have `unicorn:model` or `unicorn:action`

All changes since 0.15.0.

**v0.14.1**

- Prevent the currently focused model element from updating after the AJAX request finishes (#100).

All changes since 0.14.0.
# Introduction

## v0.14.0

- Disable poll with a component field
- Dynamically change polling options with PollUpdate
- Basic support for pydantic models

All changes since 0.13.0.

## v0.13.0

- Component key to allow disambiguation of components of the same name
- $returnValue special argument
- Get the last action method’s return value

All changes since 0.12.0.

## v0.12.0

- Redirect from action method in component

All changes since 0.11.2.

## v0.11.2

- Fix encoding issue with default component template on Windows (#91)
- Fix circular import when creating the component (#92)

All changes since 0.11.0.

## v0.11.0

- $model special argument and decorator.
- $toggle special method.
- Support nested properties when using the set shortcut.
- Fix action string arguments that would get spaces removed inadvertently.

**Breaking changes**

- All existing special methods now start with a $ to signify they are magical. Therefore, refresh is now $refresh, reset is now $reset, and validate is now $validate.

All changes since 0.10.1.

## v0.10.1

- Use LRU cache for constructed components to prevent ever-expanding memory.
- Loosen beautifulsoup4 version requirement.
- Fix bug to handle floats so that they don’t lose precision when serialized to JSON.
- Fix bug to handle related models (ForeignKeys, OneToOne, etc) fields in Django models.

All changes since 0.10.0.

## v0.10.0
• Add support for passing kwargs into the component on the template
• Provide access to the current request in the component’s methods

All changes since 0.9.4.

v0.9.4

• Fix: Prevent Django CharField form field from stripping whitespaces when used for validation.
• Fix: Handle edge case that would generate a null exception.
• Fix: Only change loading state when an action method gets called, not on every event fire.

All changes since 0.9.1.

v0.9.3

• Handle child elements triggering an event which should be handled by a parent unicorn element.

All changes since 0.9.1.

v0.9.1

• Fix: certain actions weren’t triggering model values to get set correctly

All changes since 0.9.0.

v0.9.0

• Loading states for improved UX.
• $event special argument for actions.
• u unicorn attribute.
• APPS setting for determining where to look for components.
• Add support for parent elements for non-db models.
• Fix: Handle if Meta doesn’t exist for db models.

All changes since 0.8.0.

v0.8.0

• Add much more elaborate support for dealing with Django models.

All changes since 0.7.1.

v0.7.1

• Fix bug where multiple actions would trigger multiple payloads.
• Handle lazy models that are children of an action model better.

All changes since 0.7.0.

v0.7.0

• Parse action method arguments as basic Python objects
• Stop and prevent modifiers on actions
Introduction

• Defer modifier on model
• Support for multiple actions on the same element
• Django setting for whether the JavaScript is minified

Breaking changes

• Remove unused `unicorn_styles` template tag
• Use dash for poll timing instead of dot

All changes since 0.6.5.

v0.6.5

• Attempt to get the CSRF token from the cookie first before looking at the CSRF token.

All changes since 0.6.4.

v0.6.4

• Fix bug where lazy models weren’t sending values before an action was called
• Add `is_valid` method to component to more easily check if a component has validation errors.
• Better error message if the CSRF token is not available.

All changes since 0.6.3.

v0.6.3

• Fix bug where model elements weren’t getting updated values when an action was being called during the same component update.
• Fix bug where some action event listeners were duplicated.

All changes since 0.6.2.

v0.6.2

• More robust fix for de-duping multiple actions.
• Fix bug where conditionally added actions didn’t get an event listener.

All changes since 0.6.1.

v0.6.1

• Fix model sync getting lost when there is an action (issue 39).
• Small fix for validations.

All changes since 0.6.0.

v0.6.0

• Realtime validation of a Unicorn model.
• Polling for component updates.
• More component hooks

All changes since 0.5.0.
Introduction

v0.5.0

- Call component method from JavaScript.
- Support classes, dictionaries, Django Models, (read-only) Django QuerySets properties on a component.
- Debounce modifier to change how fast changes are sent to the backend from `unicorn:model`.
- Lazy modifier to listen for `blur` instead of `input` on `unicorn:model`.
- Better support for `textarea` HTML element.

All changes since 0.4.0.

v0.4.0

- Set shortcut for setting properties.
- Listen for any valid event, not just `click`.
- Better handling for model updates when element ids aren’t unique.

All changes since 0.3.0.

v0.3.0

- Add mount hook.
- Add reset action.
- Remove lag when typing fast in a text input and overall improved performance.
- Better error handling for exceptional cases.

All changes since 0.2.3.

v0.2.3

- Fix for creating default folders when running `startunicorn`.

All changes since 0.2.2.

v0.2.2

- Set default `template_name` if it’s missing in component.

All changes since 0.2.1.

v0.2.1

- Fix `startunicorn` Django management command.

All changes since 0.2.0.

v0.2.0

- Switch from `Component` class to `UnicornView` to follow the conventions of class-based views.
- Investigate using class-based view instead of the custom `Component` class

All changes since 0.1.1.

v0.1.1
FAQ

- Fix package readme and repository link.
  All changes since 0.1.0.

**v0.1.0**

- Initial version with basic functionality.

**FAQ**

**Do I need to learn a new frontend framework for Unicorn?**

Nope! Unicorn gives you some magical template tags and HTML attributes to sprinkle in normal Django HTML templates. The backend code is a simple class that ultimately derives from `TemplateView`. Keep using the same Django HTML templates, template tags, filters, etc and the best-in-class Django ORM without learning another new framework of the week.

**Do I need to build an entire API to use Unicorn?**

Nope! Django REST framework is pretty magical on its own, and if you will need a mobile app or other use for a REST API, it’s a great set of abstractions to follow REST best practices. But, it can be challenging implementing a robust API even with Django REST framework. And I wouldn’t even attempt to build an API up from scratch unless it was extremely limited.

**Do I need to need to install GraphQL to use Unicorn?**

Nope! GraphQL looks like an awesome technology for specific use-cases and solves some pain points around creating a RESTful API. But, it is another piece of technology to wrestle with.

**Do I need to run an annoying separate node.js process or learn any tedious Webpack configuration incantations to use Unicorn?**

Nope! Unicorn installs just like any normal Django package and is seamless to implement. There are a few “magic” attributes to sprinkle into a Django HTML template, but other than that it’s just like building a regular server-side application.

**Does this replace Vue.js or React?**

Nope! In some cases, you might need to actually build an SPA in which case Unicorn really isn’t that helpful. In that case you might have to invest the time to learn a more involved frontend framework. Read Using VueJS alongside Django for one approach, or check out other articles about this.

**Isn’t calling an AJAX endpoint on every input slow?**

Not really! Unicorn is ideal for when an AJAX call would already be required (such as hitting an API for typeahead search or update data in a database). If that isn’t required, the lazy and debounce modifiers can also be used to prevent an AJAX call on every change.

**But, what about security?**

Unicorn follows the best practices of Django and requires a CSRF token to be set on any page that has a component. This ensures that no nefarious AJAX POSTs can be executed. Unicorn also creates a unique component checksum with the Django secret key on every data change which also ensures that all updates are valid.
What browsers does Unicorn support?

Unicorn mostly targets modern browsers, but any PRs to help support legacy browsers would be appreciated.

How to make sure that the new JavaScript is served when a new version of Unicorn is released?

Unicorn works great using whitenoise to serve static assets with a filename based on a hash of the file. CompressedManifestStaticFilesStorage works great for this purpose and is used by django-unicorn.com for this very purpose. Example code can be found at https://github.com/adamghill/django-unicorn.com/.

What is the difference between Unicorn and lighter front-end frameworks like htmx or alpine.js?

htmx and alpine.js are great libraries to provide interactivity to your HTML. Both of those libraries are generalized front-end framework that you could use with any server-side framework (or just regular HTML). They are both well-supported, battle-tested, and answers to how they work are probably Google-able (or on Stackoverflow).

Unicorn isn’t in the same league as either htmx or alpine.js. But, the benefit of Unicorn is that it is tightly integrated with Django and it should “feel” like an extension of the core Django experience. For example:

- redirecting from an action uses the Django redirect shortcut
- validation uses Django forms
- Django Models are tightly integrated
- Django messages “just work” the way you would expect them to
- you won’t have to create extra URLs/views for AJAX calls to send back HTML because Unicorn handles all of that for you

Installation

Install Unicorn

Install Unicorn the same as any other Python package (preferably into a virtual environment).

```
pip install django-unicorn
```

OR

```
poetry add django-unicorn
```

Note

If attempting to install django-unicorn and orjson is preventing the installation from succeeding, check whether it is using 32-bit Python. Unfortunately, orjson is only supported on 64-bit Python. More details in issue #105.

Integrate Unicorn with Django

1. Add the required apps to the INSTALLED_APPS list in the Django settings file (normally settings.py).

```
# settings.py
INSTALLED_APPS = (
    # other apps
    "django_unicorn",  # required for Django to register urls and templatetags
    # un-comment the next line once you have added your first Unicorn component
)```
Components

2. Add `path("unicorn/", include("django_unicorn.urls"))`, into the project's `urls.py`.

3. Add `{% load unicorn %}` to the top of the Django HTML template.

4. Add `{% unicorn_scripts %}` into the Django HTML template and make sure there is a `{% csrf_token %}` in the template as well.

Then, create a component.

Components

Unicorn uses the term “component” to refer to a set of interactive functionality that can be put into templates. A component consists of a Django HTML template with specific tags and a Python view class which provides the backend code for the template.

Create a component

The easiest way to create your first component is to run the following Django management command after Unicorn is installed.

```
python manage.py startunicorn hello-world
```

Warning

If this is the first component you create, you will also need to make sure that "unicorn", is in the INSTALLED_APPS list in your Django settings file (normally settings.py) to make sure that Django can find the created component templates.

Also, make sure that there is a `{% csrf_token %}` in your HTML somewhere to prevent cross-site scripting attacks while using Unicorn.

Note

Change which apps Unicorn looks in for components with the APPS setting.

Add `{% unicorn 'hello-world' %}` into the template where you want to load the new component.
Components

**Component key**

If there are multiple of the same components on the page, a key kwarg can be passed into the template. For example, `{% unicorn 'hello-world' key='helloWorldKey' %}`.

**Component arguments**

kwargs can be passed into the unicorn templatetag from the template. The kwargs will be available in the component __init__ method.

**Warning**

When overriding __init__ calling `super().__init__(**kwargs)` is required for the component to initialize properly.

```
# hello_world.py
from django_unicorn.components import UnicornView

class HelloWorldView(UnicornView):
    name = "World"

    def __init__(self, *args, **kwargs):
        super().__init__(**kwargs)  # calling super is required
        self.name = kwargs.get("name")

<!-- index.html -->
{% unicorn 'hello-world' name="Universe" %}
```

Regular Django template variables can also be passed in as an argument as long as it is available in the template context.

```
# views.py
from django.shortcuts import render

def index(request):
    context = {"hello": {"world": {"name": "Galaxy"}}}  
    return render(request, "index.html", context)

<!-- index.html -->
{% unicorn 'hello-world' name=hello.world.name %}
```

**Example component**

A basic example component could consist of the following template and class.

```
# hello_world.py
from django_unicorn.components import UnicornView

class HelloWorldView(UnicornView):
    name = "World"

<!-- hello-world.html -->
<div>
    <input unicorn:model="name" type="text" id="text" /><br />
    Hello {{ name|title }}
</div>
```
**Components**

unicorn:model is the magic that ties the input to the backend component. The Django template variable can use any property or method on the component as if they were context variables passed in from a view. The attribute passed into unicorn:model refers to the property in the component class and binds them together.

**Note**

By default unicorn:model updates are triggered by listening to input events on the element. To listen for the blur event instead, use the lazy modifier.

When a user types into the text input, the information is passed to the backend and populates the component class, which is then used to generate the output of the template HTML. The template can use any normal Django templatetags or filters (e.g. the title filter above).

**Unicorn attributes**

Attributes used in component templates usually start with unicorn:, however the shortcut u: is also supported. So, for example, unicorn:model could also be written as u:model.

**Supported property types**

Properties of the component can be of many different types, including str, int, list, dictionary, Decimal, Django Model, Django QuerySet, dataclass, or custom classes.

**Property type hints**

Unicorn will attempt to cast any properties with a type hint when the component is hydrated.

```python
# rating.py
from django_unicorn.components import UnicornView
class RatingView(UnicornView):
    rating: float = 0
def calculate_percentage(self):
    print(self.rating / 100.0)
```

Without rating: float, when calculate_percentage is called Python will complain with an error message like the following.

```
TypeError: unsupported operand type(s) for /: 'str' and 'int'
```

**Accessing nested fields**

Fields in a dictionary or Django model can be accessed similarly to the Django template language with “dot-notation”.

```python
# hello_world.py
from django_unicorn.components import UnicornView
from book.models import Book
class HelloWorldView(UnicornView):
    book = Book.objects.get(title='American Gods')
    book_ratings = {'excellent': {'title': 'American Gods'}}
```

```
<!-- hello-world.html -->
<div>
<input unicorn:model="book.title" type="text" id="model" />
<input unicorn:model="book_ratings.excellent.title" type="text"
```
Note

Django models has many more details about using Django models in Unicorn.

Django QuerySet

Django QuerySet can be referenced similarly to the Django template language in a `unicorn:model`.

```python
# hello_world.py
from django_unicorn.components import UnicornView
from book.models import Book

class HelloWorldView(UnicornView):
    books = Book.objects.all()

<!-- hello-world.html -->
<input unicorn:model="books.0.title" type="text" id="text" />
</div>
```

Note

Django models has many more details about using Django QuerySets in Unicorn.

Custom class

Custom classes need to define how they are serialized. If you have access to the object to serialize, you can define a `to_json` method on the object to return a dictionary that can be used to serialize. Inheriting from `unicorn.components.UnicornField` is a quick way to serialize a custom class, but note that it just calls `self.__dict__` under the hood, so it is not doing anything particularly smart.

Another option is to set the `form_class` on the component and utilize Django’s built-in forms and widgets to handle how the class should be deserialized. More details are provided in validation.

```python
# hello_world.py
from django_unicorn.components import UnicornView, UnicornField

class Author(UnicornField):
    def __init__(self):
        self.name = 'Neil Gaiman'

    # Not needed because inherited from `UnicornField`
    # def to_json(self):
    #     return {'name': self.name}

class HelloWorldView(UnicornView):
    author = Author()

<!-- hello-world.html -->
<div>
    <!-- Your input fields here -->
</div>
```
### Templates

Templates are just normal Django HTML templates, so anything you could normally do in a Django template will still work, including template tags, filters, loops, if statements, etc.

### Warning

Unicorn requires there to be one root element surrounding the component template.

### Model modifiers

#### Lazy

To prevent updates from happening on every input, you can append a `lazy` modifier to the end of `unicorn:model`. That will only update the component when a blur event happens.

```html
<!-- waits-for-blur.html -->
<div>
  <input unicorn:model.lazy="name" type="text" id="name" />
  Hello {{ name|title }}
</div>
```

#### Debounce

The `debounce` modifier configures how long to wait to fire an event. The time is always specified in milliseconds, for example: `unicorn:model.debounce-1000` would wait for 1000 milliseconds (1 second) before firing the message.

```html
<!-- waits-1-second.html -->
<div>
  <input unicorn:model.debounce-1000="name" type="text" id="name" />
  Hello {{ name|title }}
</div>
```

#### Defer

The `defer` modifier will store and save model changes until the next action gets triggered. This is useful to prevent additional network requests until an action is triggered.

```html
<!-- defer.html -->
<div>
  <input unicorn:model.defer="task" type="text" id="task" />
  <button unicorn:click="add">Add task</button>
  <ul>
    {% for task in tasks %}
      <li>{{ task }}</li>
    {% endfor %}
  </ul>
</div>
```
Chaining modifiers

Lazy and debounce modifiers can even be chained together.

```html
<!-- waits-for-blur-and-then-5-seconds.html -->
<div>
  <input unicorn:model.lazy.debounce-5000="name" type="text" id="text" />
  Hello {{ name|title }}
</div>
```

Key

Smooth updates

Setting a unique `id` on elements with `unicorn:model` will prevent changes to an input from being choppy when there are lots of updates in quick succession.

```html
<!-- choppy-updates.html -->
<input type="text" unicorn:model="name"></input>
```

```html
<!-- smooth-updates.html -->
<input type="text" id="someFancyId" unicorn:model="name"></input>
```

However, setting the same `id` on two elements with the same `unicorn:model` won’t work. The `unicorn:key` attribute can be used to make sure that the elements can be synced as expected.

```html
<!-- missing-updates.html -->
<input type="text" id="someFancyId" unicorn:model="name"></input>
<input type="text" id="someFancyId" unicorn:model="name"></input>
```

```html
<!-- this-should-work.html -->
<input type="text" id="someFancyId" unicorn:model="name"></input>
<input type="text" id="someFancyId" unicorn:model="name" unicorn:key="someFancyKey"></input>
```

DOM merging

The JavaScript library used to merge changes in the DOM, `morphdom`, uses an element’s `id` to intelligently update DOM elements. If it isn’t possible to have an `id` attribute on the element, `unicorn:key` will be used if it is available.

Ignore elements

Some JavaScript libraries will change the DOM (such as Select2) after the page renders. That can cause issues for Unicorn when trying to merge that DOM with what Unicorn thinks the DOM should be. `unicorn:ignore` can be used to prevent Unicorn from morphing that element or its children.

Note

When the component is initially rendered, normal Django template functionality can be used.
Actions

Components can also trigger methods from the templates by listening to any valid event type. The most common events would be click, input, keydown, keyup, and mouseenter, but MDN has a list of all of the browser event types available.

Events

An example action to call the clear_name method on the component.

```html
<!-- clear-name.html -->
<div>
  <input unicorn:model="name" type="text" id="text" />
  Hello {{ name|title }}
  <button unicorn:click="clear_name">Clear Name</button>
</div>
```

```python
# clear_name.py
from django_unicorn.components import UnicornView

class ClearNameView(UnicornView):
    name = "World"
```
def clear_name(self):
    self.name = ""

When the button is clicked, the name property will get set to an empty string. Then, the component will intelligently re-render itself and the text input will update to match the property on the component.

Tip

Instance methods without arguments can be called from the template with or without parenthesis.

Passing arguments

Actions can also pass basic Python types to the backend component.

<!-- passing-args.html -->

```html
<div>
  <input unicorn:model="name" type="text" id="text" />
  Hello {{ name|title }}
  <button unicorn:click="set('Bob')">Set as Bob</button>
  <button unicorn:click="set()">Set default value of name argument</button>
</div>
```

# passing_args.py
from django_unicorn.components import UnicornView
class PassingArgsView(UnicornView):
    name = "World"
    def set(self, name="Universe"):
        self.name = name

Argument types

Arguments can be most basic Python types, including string, int, float, list, tuple, dictionary, set, datetime, and UUID4.

<!-- argument-types.html -->

```html
<div>
  <button unicorn:click="update(99)">Pass int</button>
  <button unicorn:click="update(1.234)">Pass float</button>
  <button unicorn:click="update({'key': 'value'})">Pass dictionary</button>
  <button unicorn:click="update([1, 2, 3])">Pass list</button>
  <button unicorn:click="update((1, 2, 3))">Pass tuple</button>
  <button unicorn:click="update({1, 2, 3})">Pass set</button>
  <button unicorn:click="update(2020-09-12T01:01:01)">Pass datetime</button>
  <button unicorn:click="update(90144cb9-fc47-476d-b124-d543b0cff091)">Pass UUID</button>
</div>
```

Note

Strings will be converted to datetime if they are successfully parsed by Django's parse_datetime method.
Actions

**Set shortcut**

Actions can also set properties without requiring an explicit method.

```html
<div>
  <input unicorn:model="name" type="text" id="text" />
  Hello {{ name|title }}
  <button unicorn:click="name='Bob'">Set name as Bob</button>
</div>
```

```python
# set_shortcut.py
from django_unicorn.components import UnicornView

class SetShortcutView(UnicornView):
    name = "World"
```

**Modifiers**

Similar to models, actions also have modifiers which change how the method gets called.

**prevent**

Prevents the default action the browser would use for that element. The same as calling `preventDefault`.

```html
<!-- prevent-modifier.html -->
<div>
  <button unicorn:click.prevent="name='Bob'">Set name as Bob</button>
</div>
```

**stop**

Stops the event from bubbling up the event chain. The same as calling `stopPropagation`.

```html
<!-- stop-modifier.html -->
<div>
  <button unicorn:click.stop="name='Bob'">Set name as Bob</button>
</div>
```

**discard**

Discards any model updates from being saved before calling the specified method on the view. Useful for a cancel button.

```html
<!-- discard-modifier.html -->
<div>
  <input type="text" unicorn:model="name">
  <button unicorn:click.discard="cancel">Cancel</button>
</div>
```

```python
# discard_modifier.py
from django_unicorn.components import UnicornView

class DiscardModifierView(UnicornView):
    name = None

    def cancel(self):
        pass
```
Special arguments

$event

A reference to the event that triggered the action.

```html
<--- event.html -->
<div>
  <input type="text" unicorn:change="update($event.target.value.trim())">Update</input>
</div>
```

$returnValue

A reference to the last return value from an action method.

```html
<--- returnValue.html -->
<div>
  <input type="text" unicorn:change="update($returnValue.trim())">Update</input>
</div>
```

Special methods

$refresh

Refresh and re-render the component from its current state.

```html
<--- refresh-method.html -->
<div>
  <button unicorn:click="$refresh">Refresh the component</button>
</div>
```

$reset

Revert the component to its original state.

```html
<--- reset-method.html -->
<div>
  <button unicorn:click="$reset">Reset the component</button>
</div>
```

$toggle

Toggle a field on the component. Can only be used for fields that are booleans.

```html
<--- toggle-method.html -->
<div>
  <button unicorn:click="$toggle('check')">Toggle the check field</button>
</div>
```

Tip

Multiple fields can be toggled at the same time by passing in multiple fields at a time: `unicorn:click="$toggle('check', 'another_check', 'a_third_check')"`. Nested properties are also supported: `unicorn:click="$toggle('nested.check')"`.

$validate

Validates the component.
Child components

Calling methods

Sometimes you need to trigger a method on a component from regular JavaScript. That is possible with Unicorn.call(). It can be called from anywhere on the page.

Passing arguments is also supported.

Return values

To retrieve the last action method’s return value, use Unicorn.getReturnValue().

Child components

Unicorn supports nesting components so that one component is a child of another. Since HTML is a tree structure, a component can have multiple children, but each child only has one parent.

We will slowly build a nested component example with three components: table, filter and row. The table is the parent and contains the other two components. The filter will update the parent table component, and the row will contain functionality to edit a row.

Parent component

So that Unicorn knows about the parent-child relationship, the child component must pass in a parent keyword argument with the parent’s component view.
Child components

```python
# table.py
from book.models import Book
from django_unicorn.components import UnicornView

class TableView(UnicornView):
    books = Book.objects.none()

    def mount(self):
        self.load_table()

    def load_table(self):
        self.books = Book.objects.all()[0:10]
```

**Note**

view will always be the current component’s view, so passing view into parent (i.e. parent=view) will always create the relationship correctly.

---

**Child component**

The child filter component, {% unicorn 'filter' parent=view %}, will have access to its parent through the view’s self.parent. The FilterView is using the updated method to filter the books queryset on the table component when the filter’s search model is changed.

```html
<!-- filter.html -->
<div>
    <input type="text" unicorn:model="search" />
</div>
```

```python
from django_unicorn.components import UnicornView

class FilterView(UnicornView):
    search = ""

    def updated_search(self, query):
        self.parent.load_table()

        if query:
            self.parent.books = list(filter(lambda f: query.lower() in f.title.lower(), self.parent.books))
```

**Multiple children**

If we want to encapsulate the editing and saving of a row of data, we can add in a row component as well.
Note

The discard action modifier is used on the cancel button to provide an easy way to prevent any edits from being saved.

<!-- row.html -->
<tr>
  <td>
    {% if is_editing %}
    <input type="text" unicorn:model:defer="book.author" />
    {% else %}
    {{ book.author }}
    {% endif %}
  </td>
  <td>
    {% if is_editing %}
    <input type="text" unicorn:model:defer="book.title" />
    {% else %}
    {{ book.title }}
    {% endif %}
  </td>
  <td>
    {% if is_editing %}
    <button unicorn:click="save">Save</button>
    <button unicorn:click:discard="cancel">Cancel</button>
    {% else %}
    <button unicorn:click="edit">Edit</button>
    {% endif %}
  </td>
</tr>

# row.py
from django_unicorn.components import UnicornView
class RowView(UnicornView):
  book = None
  is_editing = False

  def edit(self):
    self.is_editing = True

  def cancel(self):
    self.is_editing = False

  def save(self):
    self.book.save()
    self.is_editing = False

The changes for the table component where the row child component is added in. Views will always have a children attribute – here it is used to set is_editing to false on all rows when the table gets reloaded.

<!-- table.html -->
{% load unicorn %}
<div>
  <!-- unicorn 'filter' parent=view -->
</div>
<table>
  <thead>
    <tr>
      <!-- row.html -->
    </tr>
  </thead>
Django Models

Unicorn provides tight integration with Django Models and QuerySets to handle typical workflows.

Model

A Django Model can be used as a field on a component just like basic Python primitive types. Use unicorn:model to bind to a field of a Django Model like you would in a normal Django template.

Warning

Unicorn requires components to have a unique identifier. Normally that is handled automatically, however multiple child components with the same component name require some help.

For child components, unicorn:id is automatically created from the parent’s unicorn:id and the child’s component name. If a child component is created multiple times in the same parent, one of the following can be used to create unique identifiers:

• pass in a key keyword argument to the child component

{% unicorn 'row' parent=view book=book key=book.id %}

• pass in an id keyword argument to the child component

{% unicorn 'row' parent=view book=book id=book.id %}

• the view has an attribute named model which has either a pk or id attribute

{% unicorn 'row' parent=view model=book %}
**Warning**

Using this functionality will serialize your entire model by default and expose all of the values in the HTML source code. Do not use this particular functionality if there are properties that need to be kept private.

One option is to customize the serialization of the model into a dictionary to only expose the data that should be publicly available.

```html
<!-- model.html -->
<div>
  <input unicorn:model.defer="book.title" type="text" id="book" />
  {{ book.title }}
  <button unicorn:click="save({{ book.pk }})">Save</button>
</div>
```

```python
# model.py
from django_unicorn.components import UnicornView
from books.models import Book

class ModelView(UnicornView):
    book: Book = None

    def mount(self):
        self.book = Book.objects.all().first()

    def save(self, book_to_save: Book):
        book_to_save.delete()
```

**Note**

The model's `pk` will be used to look up the correct model if there is only one argument for an action method and it has a type annotation for a Django `Model`. To lookup by a different model field, pass a dictionary into the front-end.

```html
<button unicorn:click="delete({ 'uuid': '{{ book.uuid }}'})">Delete by uuid</button>
```

```python
def delete(self, book_to_delete: Book):
    book_to_delete.delete()
```

**QuerySet**

A Django `QuerySet` can be set to a property on a component just like a regular `list`.

```html
<!-- queryset.html -->
<div>
  {% for book in books %}
    <div>
      <div>
        <input unicorn:model.defer="books.{{ forloop.counter0 }}.title" type="text" id="title" />
        {{ book.title }}
      </div>
      <div>
        <input unicorn:model.defer="books.{{ forloop.counter0 }}.description" type="text" id="description" />
        {{ book.description }}
      </div>
    </div>
  {% endfor %}
</div>
```
Validation

Warning

This will expose all of the model values for the QuerySet in the HTML source. One way to avoid leaking all model information is to pass the fields that are publicly viewable into values() on your QuerySet.

```python
def mount(self):
    self.books = Book.objects.all().order_by("-id")[:5]
```

A QuerySetType type hint can also be used for QuerySet to ensure the correct type is used for the component field.

```python
from django_unicorn.components import QuerySetType, UnicornView
from books.models import Book

class QuerysetView(UnicornView):
    books: QuerySetType[Book] = None

    def mount(self):
        self.books = Book.objects.all().order_by("-id")[:5]

    def save(self, book_idx: int):
        self.books[book_idx].save()
```

Validation

Unicorn uses Django forms infrastructure for all validation. This means that a form could be re-used between any other Django views and a Unicorn.

Using the Django forms system provides a way to serialize/deserialize certain classes (for example, datetime and uuid) and a way to validate properties of a class.

Note

There are many built-in fields available for Django form fields which can be used to validate text inputs.
Because of the `form_class = BookForm` defined on the `UnicornView` above, Unicorn will automatically validate that the title has a value and is less than 100 characters. The `publish_date` will also be converted into a `datetime` from the string representation in the text input.

### Showing validation errors

As the form is filled out the appropriate inputs will be validated. There are a few ways to show the validation messages.

#### Highlighting the invalid form

When a model form is invalid, a special `unicorn:error` attribute is added to the element. Depending on whether it is an invalid or required error code, the attribute will be `unicorn:error:invalid` or `unicorn:error:required`. The value of the attribute will be the validation message.
**Showing a specific error message**

```html
<!-- show-error-message.html -->
<div>
  <input unicorn:model="publish_date" type="text" id="publish-date" /><br />
  <span class="error">{{ unicorn.errors.publish_date.0.message }}</span>
</div>
```

**Showing all the error messages**

There is a `unicorn_errors` template tag that shows all errors for the component. It should provide an example of how to display component errors in a more specific way if needed.

```html
<!-- show-all-error-messages.html -->
{% load unicorn %}

<div>
  {{ unicorn_errors }}
</div>
```

**Validate the entire component**

The magic action method `$validate` can be used to validate the whole component by the front-end.

```html
<!-- validate.html -->
<div>
  <input unicorn:model="publish_date" type="text" id="publish-date" /><br />
  <button unicorn:click="$validate">Validate</button>
</div>
```

The `validate` method can also be used inside of the component.

```python
# validate.py
from django_unicorn.components import UnicornView
from django import forms

class BookForm(forms.Form):
    title = forms.CharField(max_length=6, required=True)

class BookView(UnicornView):
    form_class = BookForm

    text = "hello"

    def set_text(self):
        self.text = "hello world"
        self.validate()
```

The `is_valid` can also be used inside of the component to check if a component is valid.

```python
# validate.py
from django_unicorn.components import UnicornView
from django import forms

class BookForm(forms.Form):
    title = forms.CharField(max_length=6, required=True)

class BookView(UnicornView):
    form_class = BookForm
```
Redirecting

Unicorn has a few different ways to redirect from an action method.

Redirect

To redirect the user, return a `HttpResponseRedirect` from an action method. Using the Django shortcut `redirect` method is one way to do that in a typical Django manner.

Note

django.shortcuts.redirect can take a Django model, Django view name, an absolute url, or a relative url. However, the permanent kwarg for redirect has no bearing in this context.

Tip

It is not required to use django.shortcuts.redirect. Anything that returns a `HttpResponseRedirect` will behave the same in Unicorn.

```python
# redirect.py
from django.shortcuts import redirect
from django_unicorn.components import UnicornView
from .models import Book

class BookView(UnicornView):
    title = ""

    def save_book(self):
        book = Book(title=self.title)
        book.save()
        self.reset()

        return redirect(f'/book/{book.id}')
```

HashUpdate

To avoid a server-side page refresh and just update the hash at the end of the url, return `HashUpdate` from the action method.

```python
# hash_update.py
from django_unicorn.components import HashUpdate, UnicornView
from .models import Book
```
class BookView(UnicornView):
    title = ""

    def save_book(self):
        book = Book(title=self.title)
        book.save()
        self.reset()

        return HashUpdate(f"#{book.id}")

<!-- hash-update.html -->
<div>
    <input unicorn:model="title" type="text" id="title" />
    <br />
    <button unicorn:click="save_book()">Save book</button>
</div>

---

**LocationUpdate**

To avoid a server-side page refresh and update the whole url, return a LocationUpdate from the action method. LocationUpdate is instantiated with a HttpResponseRedirect arg and an optional title kwarg.

**Note**

LocationUpdate uses window.history.pushState so the new url must be relative or the same origin as the original url.

# location_update.py

```python
from django.shortcuts import redirect
from django_unicorn.components import LocationUpdate, UnicornView
from .models import Book

class BookView(UnicornView):
    title = ""

    def save_book(self):
        book = Book(title=self.title)
        book.save()
        self.reset()

        return LocationUpdate(redirect(f"/book/{book.id}"), title=f"{book.title}")
```

<!-- location-update.html -->
<div>
    <input unicorn:model="title" type="text" id="title" />
    <br />
    <button unicorn:click="save_book()">Save book</button>
</div>

---

**Loading States**

Unicorn requires an AJAX request for any component updates, so it is helpful to provide some context to the user that an action is happening.

**Toggling Elements**

Elements with the unicorn:loading attribute are only visible when an action is in process.
When the *Update* button is clicked, the “Updating!” message will show until the action is complete, and then it will re-hide itself.

### Warning

Loading elements get shown or removed with the `hidden` attribute. One drawback to this approach is that setting the style `display` property overrides this functionality.

You can also hide an element while an action is processed by adding a `remove` modifier.

If there are multiple actions that happen in the component, you can show or hide a loading element for a specific action by targeting another element’s `id` with `unicorn:target`.

An element’s `unicorn:key` can also be targeted.

**Toggling Attributes**

Elements with an action event can also include an `unicorn:loading` attribute with either an `attr` or `class` modifier.

**attr**

Set the specified attribute on the element that is triggering the action. This example will disable the *Update* button when it is clicked and remove the attribute once the action is completed.
Dirty States

Add the specified class(es) to the element that is triggering the action.

This example will add loading and spinner classes to the Update button when it is clicked and remove the classes once the action is completed.

<!-- loading-class.html -->
<div>
  <button unicorn:click="update" unicorn:loading.attr="disabled">Update</button>
</div>

Remove the specified class from the element that is triggering the action.

This example will remove an active class from the Update button when it is clicked and add the class back once the action is completed.

<!-- loading-class-remove.html -->
<div>
  <button unicorn:click="update" unicorn:loading.class.remove="active">Update</button>
</div>

Dirty States

Unicorn can provide context to the user that some data has been changed and will be updated.

**Toggling Attributes**

Elements can include an unicorn:dirty attribute with either an attr or class modifier.

**attr**

Set the specified attribute on the element that is changed.

This example will set the input to be readonly when the model is changed. The attribute will be removed once the name is synced or if the input value is changed back to the original value.

<!-- dirty-attr.html -->
<div>
  <input unicorn:model="name" unicorn:dirty.attr="readonly" />
</div>

Add the specified class(es) to the model that is changed.

This example will add dirty and changing classes to the input when the model is changed. The classes will be removed once the model is synced or if the input value is changed back to the original value.

<!-- dirty-class.html -->
<div>
  <input unicorn:model="name" unicorn:dirty.class="dirty changing" />
</div>
class.remove

Remove the specified class(es) from the model that is changed.

This example will remove the `clean` class from the input when the model is changed. The class will be added back once the model is synced or if the input value is changed back to the original value.

```html
<!-- dirty-class-remove.html -->
<div>
  <input unicorn:model="name" unicorn:dirty.class.remove="clean" />
</div>
```

Partial Updates

Normally Unicorn will send the entire component’s rendered HTML on every action to make sure that any changes to the context is reflected on the page. However, to reduce latency and minimize the amount of data that has to be sent over the network, Unicorn allows actions to only update a portion of the page through the `unicorn:partial` attribute.

**Note**

By default, `unicorn:partial` will look in the current component’s template for an `id` or `unicorn:key`. If an element can’t be found with the specified target, the entire component will be morphed like usual.

```python
# partial_update.py
from django_unicorn.components import UnicornView

class PartialUpdateView(UnicornView):
    checked = False
```

```html
<!-- partial-update.html -->
<div>
  <span id="checked-id">{{ checked }}</span>
  <button unicorn:click="$toggle('checked')" unicorn:partial="checked-id">
    Toggle checked
  </button>
</div>
```

**Target by id**

To only target an element `id` add the `id` modifier to `unicorn:partial`.

```html
<!-- partial-update-id.html -->
<div>
  <span id="checked-id">{{ checked }}</span>
  <button unicorn:click="$toggle('checked')" unicorn:partial.id="checked-id">
    Toggle checked
  </button>
</div>
```

**Target by key**

To only target an element `unicorn:key` add the `key` modifier to `unicorn:partial`.

```html
<!-- partial-update-key.html -->
<div>
  <span unicorn:key="checked-key">{{ checked }}</span>
  <button unicorn:click="$toggle('checked')" unicorn:partial.key="checked-key">
    Toggle checked
  </button>
</div>
```
Polling

unicorn:poll can be added to the root div element of a component to have it refresh the component automatically every 2 seconds. The polling is smart enough that it won’t poll when the page is inactive.

```python
from django.utils.timezone import now
from django_unicorn.components import UnicornView

class PollingView(UnicornView):
    current_time = now()

<!-- polling.html -->
<div unicorn:poll>{{ current_time }}</div>
```

A method can also be specified if there is a specific method on the component that should be called every time the polling fires. For example, unicorn:poll="get_updates" would call the get_updates method instead of the built-in refresh method.

To define a different refresh time in milliseconds, a modifier can be added as well. unicorn:poll-1000 would fire the refresh method every 1 second, instead of the default 2 seconds.

```html
<!-- polling_every_five_seconds.html -->
<div unicorn:poll-1000="get_updates">
    <input unicorn:model="update" type="text" id="text" />
    {{ update }}
</div>
```

Disable poll

Polling can dynamically be disabled by checking a boolean field from the component.

```python
from django.utils.timezone import now
from django_unicorn.components import UnicornView

class PollDisableView(UnicornView):
    polling_disabled = False
    current_time = now()

def get_date(self):
    self.current_time = now()

<!-- poll-disable.html -->
<div unicorn:poll-1000="get_date" unicorn:poll.disable="polling_disabled">
    current_time: {{ current_time|date:"s" }}<br />
    <button u:click="$toggle('polling_disabled')">Toggle Polling</button>
</div>
```

Note

The field passed into unicorn:poll.disable can be negated with an exclamation point.

```python
from django.utils.timezone import now
from django_unicorn.components import UnicornView

```
class PollDisableNegationView(UnicornView):
    polling_enabled = True
    current_time = now()

    def get_date(self):
        self.current_time = now()

<!-- poll-disable-negation.html -->
<div unicorn:poll-1000="get_date" unicorn:poll:disable="!polling_enabled">
    current_time: {{ current_time|date:"s" }}<br />
    <button u:click="$toggle('polling_enabled')">Toggle Polling</button>
</div>

PollUpdate

A poll can be dynamically updated by returning a PollUpdate object from an action method. The timing and method can be updated, or it can be disabled.

# poll_update.py
from django.utils.timezone import now
from django_unicorn.components import PollUpdate, UnicornView

class PollingUpdateView(UnicornView):
    polling_disabled = False
    current_time = now()

    def get_date(self):
        self.current_time = now()
        return PollUpdate(timing=2000, disable=False, method="get_date")

<!-- poll-update.html -->
<div unicorn:poll-1000="get_date">
    current_time: {{ current_time|date:"s" }}<br />
</div>

Messages

Unicorn supports Django messages and they work the same as if the template was rendered server-side. When the update action is fired, a success message will be added to the request and will show up inside the component.

<!-- messages.html -->
<div>
    {% if messages %}
    <ul class="messages">
        {% for message in messages %}
        <li{% if message.tags %} class="{{ message.tags }}"{% endif %}>{% message %}</li>
        {% endfor %}
    </ul>
    {% endif %}
</div>

<!-- messages.py -->
from django.contrib import messages
from django_unicorn.components import UnicornView

class MessagesView(UnicornView):
### Advanced Views

#### Class properties

**template_name**

By default, the component name is used to determine what template should be used. For example, `hello_world.HelloWorldView` would by default use `unicorn/hello-world.html`. However, you can specify a particular template by setting `template_name` in the component.

```python
from django_unicorn.components import UnicornView
class HelloWorldView(UnicornView):
    template_name = "unicorn/hello-world.html"
```

#### Instance properties

**request**

The current `request` is available on `self` in the component's methods.

```python
class HelloWorldView(UnicornView):
    def __init__(self, *args, **kwargs):
        super.__init__(**kwargs)
        print("Initial request that rendered the component", self.request)

    def test(self):
        print("callMethod request to re-render the component", self.request)
```

#### Custom methods

Defined component instance methods with no arguments are made available to the Django template context and can be called like a property.

```python
class StateView(UnicornView):
    def all_states(self):
        return ["Alabama", "Alaska", "Arizona", ...]
```

```html
{% for state in all_states %}
    <li>{{ state }}</li>
{% endfor %}
</ul>
</div>
{% endverbatim %}
```
**Tip**

If the method is intensive and will be called multiple times, it can be cached with Django’s `<a href="https://docs.djangoproject.com/en/stable/ref/utils/#django.utils.functional.cached_property">cached_property</a>` to prevent duplicate API requests or database queries. The method will only be executed once per component rendering.

```python
# states.py
from django.utils.functional import cached_property
from django_unicorn.components import UnicornView

class StateView(UnicornView):
    @cached_property
    def all_states(self):
        return ["Alabama", "Alaska", "Arizona", ...]
```

### Instance methods

#### `__init__()`

Gets called when the component gets constructed for the very first time. Note that constructed components get cached to reduce the amount of time discovering and instantiating them, so `__init__` only gets called the very first time the component gets rendered.

```python
# hello_world.py
from django_unicorn.components import UnicornView

class HelloWorldView(UnicornView):
    name = "original"

    def __init__(self, *args, **kwargs):
        super().__init__(**kwargs)
        self.name = "initialized"
```

#### `mount()`

Gets called when the component gets initialized or reset.

```python
# hello_world.py
from django_unicorn.components import UnicornView

class HelloWorldView(UnicornView):
    name = "original"

    def mount(self):
        self.name = "mounted"
```

#### `hydrate()`

Gets called when the component data gets set.

```python
# hello_world.py
from django_unicorn.components import UnicornView

class HelloWorldView(UnicornView):
    name = "original"

    def hydrate(self):
        self.name = "hydrated"
```
### updating(name, value)

Gets called before each property that will get set.

### updated(name, value)

Gets called after each property gets set.

### updating_{property_name}(value)

Gets called before the specified property gets set.

### updated_{property_name}(value)

Gets called after the specified property gets set.

### calling(name, args)

Gets called before each method that gets called.

### called(name, args)

Gets called after each method gets called.

### complete()

Gets called after all methods have been called.

### rendered(html)

Gets called after the component has been rendered.

### parent_rendered(html)

Gets called after the component’s parent has been rendered (if applicable).

### Meta

Classes that derive from `UnicornView` can include a `Meta` class that provides some advanced options for the component.

#### exclude

By default, all public attributes of the component are included in the context of the Django template and available to JavaScript. One way to protect internal-only data is to prefix the attribute name with `_` to indicate it should stay private.

```python
# hello_state.py
from django_unicorn.components import UnicornView

class HelloStateView(UnicornView):
    _all_states = (
        "Alabama",
        "Alaska",
        ...
        "Wisconsin",
        "Wyoming",
    )
```

Another way to prevent that data from being available to the component template is to add it to the `Meta` class’s `exclude` tuple.
Advanced Views

```python
# hello_state.py
from django_unicorn.components import UnicornView

class HelloStateView(UnicornView):
    all_states = (
        "Alabama",
        "Alaska",
        ...
        "Wisconsin",
        "Wyoming",
    )

class Meta:
    exclude = ("all_states", )
```

**javascript_exclude**

To allow an attribute to be included in the the context to be used by a Django template, but not exposed to JavaScript, add it to the Meta class’s javascript_exclude tuple.

```html
<!-- hello-state.html -->
<div>
    {% for state in all_states %}
    <div>{{ state }}</div>
    {% endfor %}
</div>

<!-- call-javascript.html -->
<div>
    <script>
        function hello(name) {
            alert("Hello, " + name);
        }
    </script>

    <input type="text" unicorn:model="name" />
    <button type="submit" unicorn:click="hello">Hello!</button>
</div>
```

**JavaScript Integration**

To integrate with other JavaScript functions, view methods can call an arbitrary JavaScript function after it gets rendered.

```html
<!-- call-javascript.html -->
<div>
    <script>
        function hello(name) {
            alert("Hello, " + name);
        }
    </script>

    <input type="text" unicorn:model="name" />
    <button type="submit" unicorn:click="hello">Hello!</button>
</div>
```
Queue Requests

This is an experimental feature of that queues up slow-processing component views to prevent race conditions. For simple components this should not be necessary.

Serialization is turned off by default, but can be enabled in the settings.

Warning

This feature will be disabled automatically if the cache backend is set to "django.core.cache.backends.dummy.DummyCache".

Local memory caching (the default if no CACHES setting is provided) will work fine if the web server only has one process. For more production use cases, consider using redis, Memcache, or database caching.

Settings

Unicorn stores all settings in a dictionary under the UNICORN attribute in the Django settings file. All settings are optional.

```
# settings.py
UNICORN = {
    "MINIFIED": True,
    "APPS": ["unicorn"],
    "SERIAL": {
        "ENABLED": False,
        "TIMEOUT": 60,
    },
    "CACHE_ALIAS": "default",
}
```

APPS

Specify the modules to look for components. Defaults to ["unicorn",].

CACHE_ALIAS

The alias to use for caching. Only used by the experimental serialization of requests for now. Defaults to "default".

MINIFIED

Provides a way to control if the minified version of unicorn.min.js is used. Defaults to !DEBUG.
**SERIAL**

Settings for the experimental serialization of requests. Defaults to `{}`.

**ENABLED**

Whether slow requests to the same component should be queued or not. Defaults to `False`.

**TIMEOUT**

The number of seconds to wait for a request to finish for additional requests to queue behind it. Defaults to `60`.

**CLI**

Unicorn provides a Django management command to create new components.

```bash
python manage.py startunicorn hello-world
```

The command will create a `unicorn` directory, and `templates` and `components` sub-directories if necessary. Underneath the `components` directory there will be a new module and subclass of `django_unicorn.components.UnicornView`. Underneath the `templates/unicorn` directory will be an example template.

The following is an example folder structure.

```
unicorn/
  components/
    hello_world.py
  templates/
    unicorn/
      hello-world.html
```

**Architecture**

Unicorn is made up of multiple pieces which are all integrated tightly together. The following is a summary of how some of it all fits together, although it skips over a lot of the complexity and advanced functionality. However, for all of the details the code is available at [https://github.com/adamghill/django-unicorn/](https://github.com/adamghill/django-unicorn/).

**Template tags**

Starting with the integration with a normal Django template, there are the `unicorn_scripts` and `unicorn template tags`. `unicorn_scripts` renders out the entire JavaScript library and initializes the global Unicorn object. The `unicorn template tag` provides the ability to add the component wherever it is needed on the page. Based on the name passed into the `unicorn template tag`, conventions are used to find the correct component view and component template (e.g. if "hello-world" is passed into the template tag, a class of `hello_world.HelloWorldView` and a template named `hello-world.html` will be searched for).

Once the component view and template are found, a serialized version of all of the public attributes of the component view is generated into a JSON object for the page, and the template is rendered with a context of those same public attributes.

**JavaScript initialization**

After the template is rendered, the JavaScript library parses the HTML for DOM elements that start with `unicorn:` or `u:` and creates a list of attributes that end with `:model`, `:poll`, or other specific Unicorn functionality. For attributes that are let, the assumption is that they are an event type (e.g. `unicorn:click`).

For anything that is a model, the JavaScript sets the value for the element based on the serialized data of the publicly available attributes from the component view. Event listeners are attached for all event types. Then, other custom functionality is setup (e.g. polling).
**Models**

For all inputs which have a `model` attribute, an event listener is attached (either `change` or `blur` depending on if the `lazy` modifier is used). The `defer` modifier will store the action to be bundled with an action event that might happen later.

Once a model event is fired it is sent over the wire to the defined AJAX endpoint with a specific JSON structure which tells Unicorn what the updated data from the input should be. The component class is re-instantiated and the data is updated from the front-end, then re-rendered and the HTML is returned in the response.

**Actions**

Actions follow a similar path as the models above, however there is a different JSON structure. Also, the method, arguments, and kwargs that are passed from the front-end get parsed with a mix of `ast.parse` and `ast.literal_eval` to convert the strings into the appropriate Python types (i.e. change the string “1” to the integer 1). After the component is re-initialized, the method is called with the passed-in arguments and kwargs. Once all of the actions have been called, the component view is re-rendered and the HTML is returned in the response.

**HTML Diff**

After the AJAX endpoint returns its response, the newly rendered DOM is merged into the old DOM with `morphdom` and input values are set again based on the new data in the AJAX response.

Unicorn is a reactive component framework that progressively enhances a normal Django view, makes AJAX calls in the background, and dynamically updates the DOM. It seamlessly extends Django past its server-side framework roots without giving up all of its niceties or re-building your website.

**Related projects**

Unicorn stands on the shoulders of giants, in particular `morphdom` which is integral for merging DOM changes.

**Inspirational projects in other languages**

- **Livewire**, a full-stack framework for the PHP web framework, Laravel.
- **LiveView**, a library for the Elixir web framework, Phoenix, that uses websockets.
- **StimulusReflex**, a library for the Ruby web framework, Phoenix, that uses websockets.
- **Hotwire**, “is an alternative approach to building modern web applications without using much JavaScript by sending HTML instead of JSON over the wire”. Uses AJAX, but can also use websockets.

**Full-stack framework Python packages**

- **Reactor**, a port of Elixir’s LiveView to Django. Especially interesting for more complicated use-cases like chat rooms, keeping multiple browsers in sync, etc. Uses Django channels and websockets to work its magic.
- **Flask-Meld**, a port of Unicorn to Flask. Uses websockets.
- **Sockpuppet**, a port of Ruby on Rail’s StimulusReflex. Requires Django channels and websockets.
- **Django inertia.js adapter** allows Django to use `<a href="https://inertiajs.com">inertia.js</a>` to build an SPA without building an API.
- **Hotwire for Django** contains a few different repositories to integrate Hotwire with Django.

**Django packages to integrate lightweight frontend frameworks**

- **django-htmx** which has extensions for using Django with htmx.

**Django component packages**
Related projects

- **django-components**, which lets you create “template components”, that contains both the template, the Javascript and the CSS needed to generate the front end code you need for a modern app.

- **django-component**, which provides declarative and composable components for Django, inspired by JavaScript frameworks.

- **django-page-components**, a minimalistic framework for creating page components and using them in your Django views and templates.
